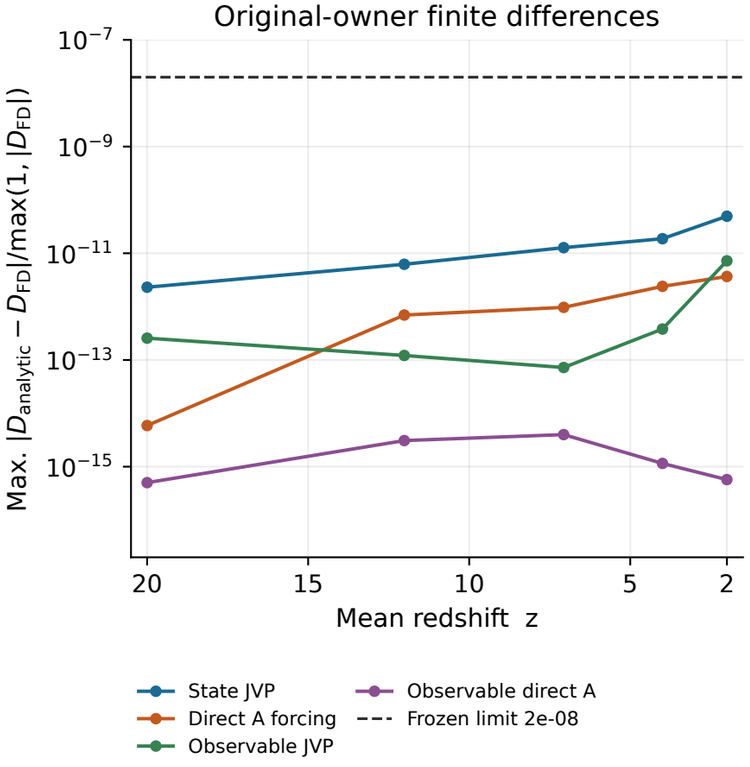
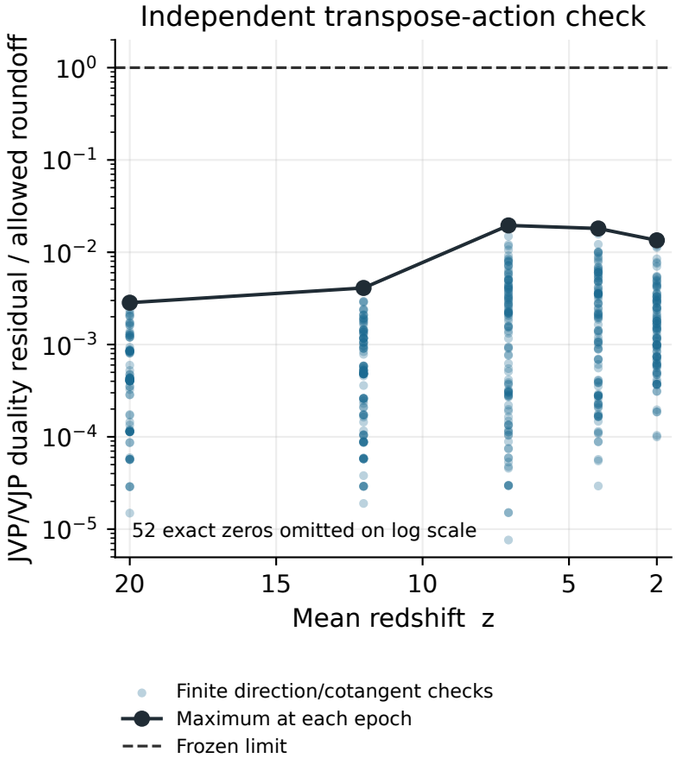
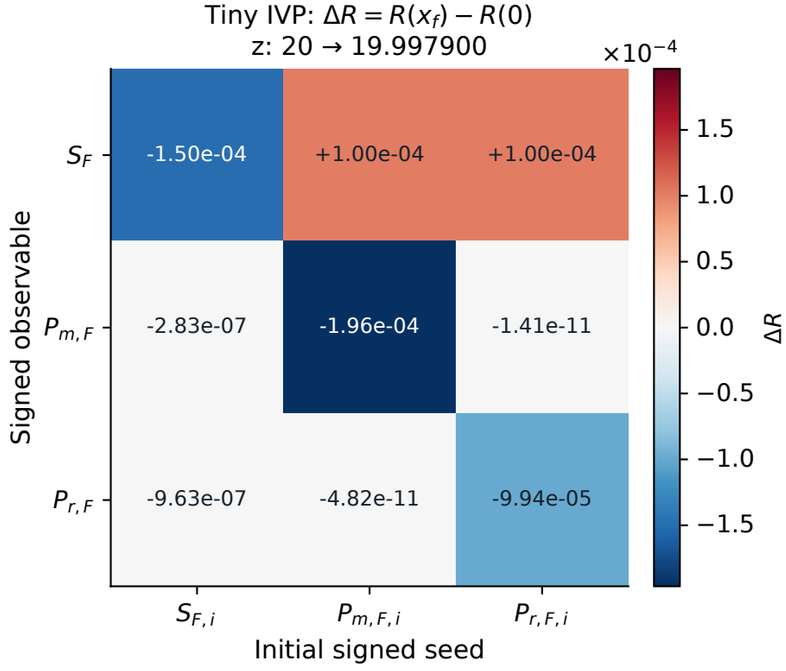
Finite-set validation and short-interval response wiring

FD: 200 stored states × 3 directions | JVP/VJP uses the stated 512-epsilon bound







$R_{ij} = \partial O_i/\partial \theta_j$ (unscaled). Synthetic seed (0.002, 0.00007, −0.0002); x ∈ [0, 0.0001], three output nodes.

The tiny run checks the implementation connection. These finite diagnostics do not certify long-window or continuum error.
