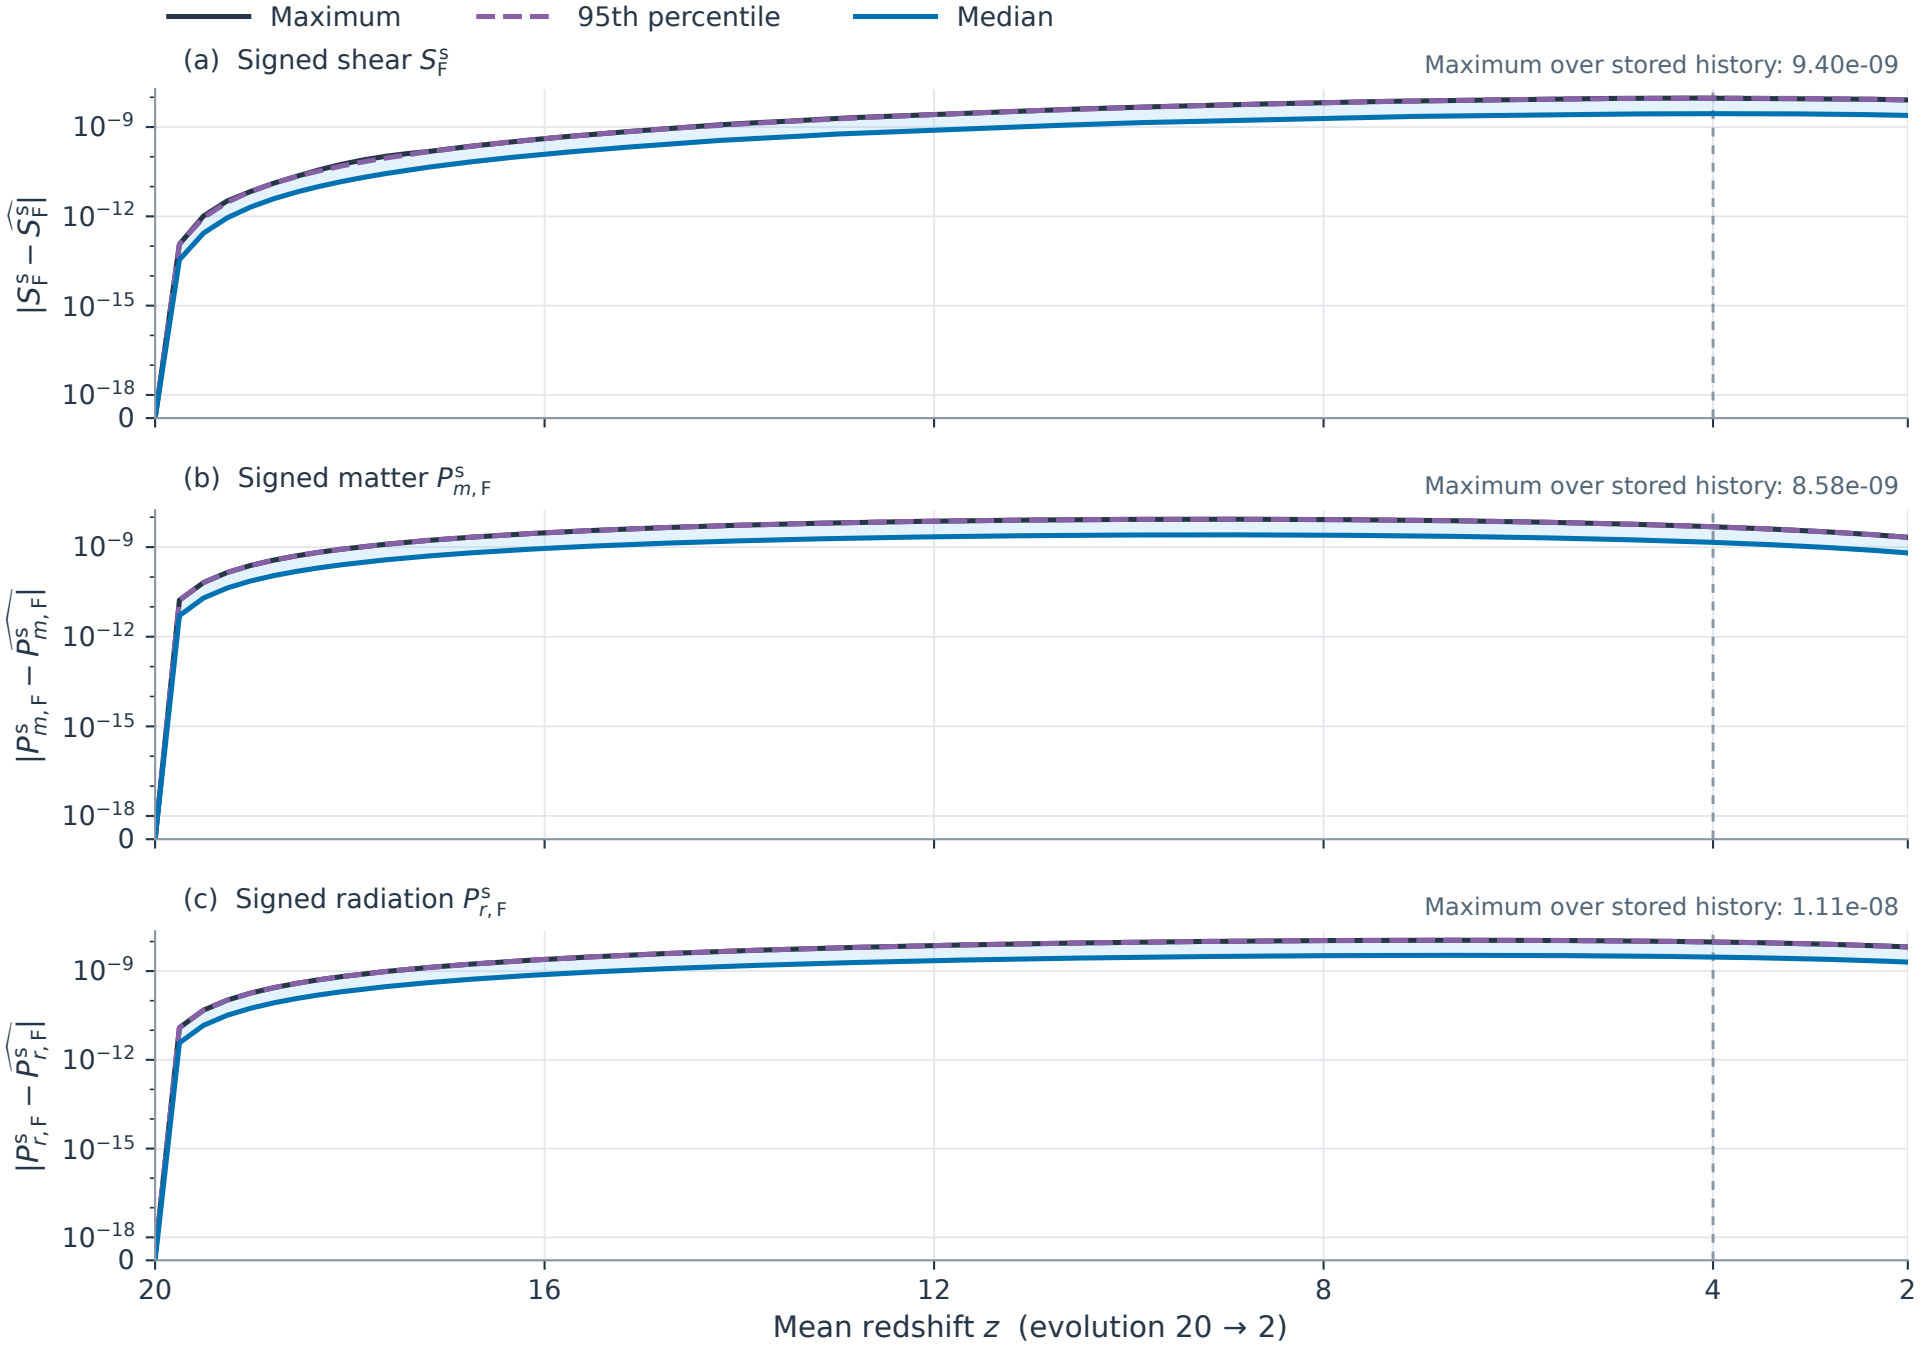
Anchored-axis reconstruction along the full history

63 axis-support trajectories reconstruct 112 mixed cases | 153 epochs | collisionless, fixed $L = 8$

$$\widehat{F}(S_i, m_i, r_i; z) = F(S_i, m_i, 0; z) + F(S_i, 0, r_i; z) - F(S_i, 0, 0; z)$$



Absolute differences of saved trajectories; quantiles are across the 112 mixed cases at each stored epoch.
Vertical scale: logarithmic above 10^{-18}, linear down to zero; no display floor. Dashed vertical line: z=4 join.
Common redshift is not common proper time. Preliminary reconstruction comparison, not an ODE or convergence error bound.
